2023/05/05 | Pi Table updation lag issue

Investigation Details:

Rule Name: GV_nonTrust_Card_1User_24H

Rule Function: Blocks transactions if they fulfill these conditions.

- MerchantId is one of: PTMPPL51090571015468, PTMPDP64805242556055
- PayMethod is one of: CREDIT_CARD; CREDIT_CARD, Balance; Balance, CREDIT_CARD; DEBIT_CARD; DEBIT_CARD, Balance; Balance, DEBIT_CARD
- If there is at least one other non trusted user has made a successful transaction using the same non trusted card in the last 24 hours

The transaction in question was done by a non trusted user and a non trusted card. We have a non trusted transaction with the same card but with a different non trusted user within 1 minute.

Attribute: gci_uid_gv_nontrust_success_1d

- Rule checks for the above attribute to find out the number of non trusted users who have done a transaction on this card.
- One non-trusted user had already done the transaction, however it was not reflected in the attribute due to delay in attribute updation.
- Within this lag another non-trusted user tried transacting with the same card and rule could not block it due to delay in attribute updation.
- Attribute was updated after 30 seconds and the rule started blocking further transaction attempts initiated on the same card.

Action Item: M* team to analyze current resources allocated to the attribute and readjust. For more details on the request : https://paytm.slack.com/archives/C019JNJH18B/p1683281245274359

Conclusion :

The bank was responding a little later than usual for these events. We use async data in Pi tables and that led to the lag in updation.
